

Performance Analysis Summary:

While running the app in debug mode, I opened Flutter Devtools and accessed the Performance tab. I then interacted with the app by doing the following in order:

1. Pressed “Get current location”
2. Toggled the notification mute button
3. Opened the Restaurant list and deleted a restaurant
4. Returned to the main screen.
5. Went to “Add restaurant” and submitted a new one
6. Then returned back to the home screen.

The performance graph captured during this session shows that most frames rendering well under the 16ms budget. However, a few spikes (jank/red bars) occurred during heavier operations like location fetching or navigating between screens. This is expected behaviour in debug mode, especially during rebuilds or animations. Overall, the UI remained smooth and responsive during typical use.

Screenshots 1-3: App launch and initial “get current location” button tap. Slight frame jank during location fetch is seen, expected due to permission checks and location services start up.

Screenshots 4-6: Navigating to restaurant list and deleting a restaurant. A few red spikes appear during navigation and state update.

Screenshots 7-9: Navigating to Add restaurant and submitting a new entry. Additional jank observed during screen transitions and database write operations.

Screenshots 10-13: Back to home screen. Most frames render smooth after initial operations.
